**Abstract.** We present the RLWE-based signature scheme, NCC-Sign, using non-cyclotomic polynomials and cyclotomic trinomials, which follows the design paradigm of Dilithium based on Bai and Galbraith scheme with public key compression. NCC-Sign uses two types of polynomial rings, based on the non-cyclotomic polynomial  $\phi(X) = X^p - X - 1$  for stronger security and the trinomial  $\phi(X) = X^n - X^{n/2} + 1$  for efficiency. It provides higher security by choosing more conservative parameters whose classical Core-SVP estimates exceed or are close to 128, 192, and 256 bits at the three security levels, respectively. NCC-Sign using the non-cyclotomic polynomial provides stronger security guarantee than power-of-2 cyclotomic counterparts by minimizing structures that can be used by attackers. However, it is inefficient since it cannot use the optimized implementation techniques for the cyclotomic power-of-2 rings. Our cyclotomic trinomial counterpart meets both conservative security and efficiency requirements.

**Keywords:** Cyclotomic field · Digital signature · Non-cyclotomic polynomial · RLWE · RSIS · Inert Modulus · Trinomial.

## 1 Introduction

Majority of efficient lattice-based schemes including NIST Post-Quantum Cryptography (PQC) Standardization Round 4 algorithms [2] are based on the structured lattices using power-of-2 cyclotomics by default. Explicitly, Kyber, Saber, Dilithium, and Falcon use the  $2n$ -th cyclotomic polynomial  $\phi(X) = X^n + 1$ , where  $n$  is a power of 2, and NTRU KEM uses the  $p$ -th cyclotomic polynomial  $\phi(X) = X^p - 1$ , where  $p$  is prime [12, 21, 20, 34, 24, 26, 28]. They achieve high speeds on several architectures as well as reasonably small signatures and key sizes.

There are advantages to choosing the cyclotomic polynomials, but there has been a potential threat of attacks using unnecessary algebraic structures [9, 14]. The attacks related to the additional algebraic structures exploit the fact that

---

<sup>\*</sup> This work is submitted to ‘Korean Post-Quantum Cryptography Competition’ ([www.kpqc.or.kr](http://www.kpqc.or.kr)).

the field  $\mathbb{Q}[X]/\phi(X)$  has many subfields for certain  $\phi(X)$  [8, 6], some attacks use the fact that a number field  $\mathbb{Q}[X]/\phi(X)$  has small Galois group [15], and some attacks use the fact that there exist ring homomorphisms from  $\mathbb{Z}_q[X]/\phi(X)$  to some smaller nonzero rings [22, 23, 16]. There is a sub-exponential time attack against NTRU assumptions with large moduli, which invalidated security guarantees of some FHE schemes [6, 32, 13]. There are also polynomial-time quantum attacks that broke Soliloquy, the cyclotomic case of Gentry’s original fully homomorphic encryption (FHE) at STOC 2009 and the cyclotomic case of the Garg-Gentry-Halevi scheme under the plausible assumptions [11].

Although no attacks are known that perform significantly better on the schemes based on the structured lattices of cyclotomics, it remains possible that further cryptanalysis could exploit the structures. Therefore, it is necessary to think about countermeasures against the potential threats. As an opponent of these cyclotomics, a lattice-based KEM, NTRU Prime KEM, was selected as one of the alternative candidates of NIST PQC Round 3 [1], but there is no such a digital signature counterpart. NTRU Prime KEM uses the NTRU Prime field [9], which aims to remove unnecessary structures exploited in attacks. Suggestions for the NTRU Prime field are as follows:

1. Choose  $\phi(X)$  as a monic irreducible polynomial of prime degree  $p$  whose Galois group is isomorphic to  $S_p$  (the largest Galois group possible).
2. Choose a prime number  $q$  such that  $\phi(X)$  is still an irreducible polynomial in  $\mathbb{Z}_q[X]$ , i.e.  $\mathbb{Z}_q[X]/\phi(X)$  becomes a field.

NTRU Prime field uses an irreducible polynomial  $\phi(X) = X^p - X - 1$  to satisfy the first condition, and the second condition was satisfied with probability  $1/p$  for a random prime modulus  $q$ .

The schemes based on unstructured lattices guarantee stronger security than those based on the structured lattices, but they suffer from much larger key sizes. Our goal is to construct a lattice-based signature scheme that achieves stronger security guarantee than cyclotomic counterparts and better efficiency than unstructured lattice-based schemes.

### 1.1 Design Rationale, Advantages and Limitations

NCC-Sign uses the non-cyclotomic polynomial  $\phi(X) = X^p - X - 1$  for stronger security and the trinomial  $\phi(X) = X^n - X^{n/2} + 1$  for efficiency. It is designed with the following design rationale.

#### [NCC-Sign Non-cyclotomic: NCC-Sign-NC]

- **A RLWE-based Signature Scheme using the Non-cyclotomic Polynomial.** NCC-Sign follows the design paradigm of Dilithium based on Bai and Galbraith scheme with public key compression. It uses a prime-degree large Galois group inert modulus with  $\phi(X) = X^p - X - 1$ , which allows to eliminate the structures that were the causes of the previous attacks in the power-of-2 cyclotomic cases. Its existential unforgeability of our scheme

is proved in (Q)ROM under the RLWE, RSIS and SelfTargetRSIS assumptions in a similar way to Dilithium [20, 34]. Unlike Dilithium based on the MLWE/MSIS problems over the power-of-2 cyclotomic ring, NCC-Sign is based on the RLWE/RSIS problems over the non-cyclotomic polynomial ring. Such a choice leads to selection of more conservative parameters for higher security.

- **Intermediate Security Guarantee.** In terms of the potential attacks, the schemes based on non-cyclotomic polynomials are more confidence than their ring and module counterparts. NTRU Prime KEM [9, 14] presented evidences that non-cyclotomic scheme had lower risks against the related classical and quantum attacks than the cyclotomic counterparts. NCC-Sign provides intermediate security guarantees between unstructured lattices and cyclotomic structured lattices against the potential threats.
- **A New Optimized SampleInBall.** We propose a new optimized SampleInBall to choose the challenge polynomial in signing and verification algorithms using two different polynomials. This algorithm provides speed-up ranging from 9% to 15% in the rejection sampling phase, depending on the parameter sets.
- **Flexible Choice of Parameters and Conservative Security.** In the RLWE and MLWE-based schemes over the power-of-2 cyclotomic ring, the degree of polynomials must jump in increasingly by doubling or 256, respectively. NCC-Sign provides flexibility in the parameter selection without any jumps appearing in the schemes. We select flexible conservative parameter sets whose classical Core-SVP estimates nearly equal or exceed 128, 192, and 256 bits at the three security levels, 1, 3, and 5, respectively. Particularly, the expected number of repetitions in the rejection samplings of NCC-Sign are up to 50% of Dilithium.
- **Protection against Side-Channel Attacks.** NCC-Sign uses uniform sampling to prevent the side-channel attacks targeting the discrete Gaussian distribution. All key dependent operations in our scheme are performed in a constant-time manner.

NCC-Sign using non-cyclotomic rings ensures stronger security guarantee against the potential threat, but is inefficient since it cannot use the optimized implementation techniques for the power-of-2 cyclotomic rings. Our cyclotomic trinomial counterpart meets both conservative security and efficiency requirement.

#### [NCC-Sign Trinomial: NCC-Sign-T]

- **A RLWE-based Signature Scheme using the Trinomial.** Our trinomial counterpart uses the  $m$ -th cyclotomic trinomial  $\phi(X) = X^n - X^{n/2} + 1$ , where  $m = 2^a \cdot 3^b$ ,  $a, b \geq 1$  and  $n = \phi(m) = m/3$ . The use of the trinomials with the extended form of degree  $n = 2^a \cdot 3^b$  provides sufficient candidates of possible degrees which allows for choosing more conservative parameters for higher security.

- **Flexible Choice of Parameters and Conservative Security.** The trinomial with the extended form of degree allows use to select flexible parameter selection for conservative security avoiding the parameter jump appeared in the RLWE-based schemes on the power-of-2 rings. While the classical Core-SVP estimates of Dilithium parameter sets are 123, 182, and 252 bits at the three security levels, respectively, those of our parameter sets exceed or are close to 128, 192, and 256 bits at the three security levels, respectively.
- **Fast Performance on Cortex-M4.** NCC-Sign-T is faster than NCC-Sign-NC. Although it uses larger degrees than Dilithium for higher security, its reference implementation is faster than that of Dilithium. Compared to Dilithium, AVX2-optimized implementation of NCC-Sign-T is faster than Dilithium at the security level 3, sign of NCC-Sign-T is 21% faster than Dilithium at the security level 1, and key generation of NCC-Sign-T is 18% faster than Dilithium at the security level 5. The rest of NCC-Sign-T are similar to or slower Dilithium. However, optimized implementation of NCC-Sign-T on the Cortex-M4 is faster than Dilithium: key generation, sign, and verify of NCC-Sign-T are at least 11% and at most 71% faster than those of Dilithium. It is also about 28%, 41% and 42% faster than Dilithium in terms of KeyGen+Sign+Verify at the three security levels, respectively. Faster performance of NCC-Sign-T over Dilithium is due to the fact that NCC-Sign-T based on the ring structure requires fewer polynomial coefficients than Dilithium based on the module structure, and the number of repetitions in the rejection samplings for signing in NCC-Sign-T is smaller than that of Dilithium. They result in fewer calls to SHAKE in the sampling process and fewer aborts in signing. NCC-Sign-T also shows better results than Dilithium in stack usage for all parameter sets. NCC-Sign-T is well suited for low-cost constrained devices. We believe that further performance improvements are possible if more optimization studies are conducted specifically for NCC-Sign-T.
- **Protection against Side-Channel Attacks.** Our trinomial counterpart also uses uniform sampling and its all key dependent operations are performed in a constant-time manner.

## 2 Signature Scheme: NCC-Sign

### 2.1 Basic Operations

Throughout this document, in NCC-Sign Non-cyclotomic, we let  $R := \mathbb{Z}[X]/(X^p - X - 1)$  and  $R_q := \mathbb{Z}_q[X]/(X^p - X - 1)$  for some prime numbers  $p$  and  $q$  such that  $R_q$  is a field. In NCC-Sign Trinomial, we let  $R := \mathbb{Z}[X]/(X^n - X^{n/2} + 1)$  and  $R_q := \mathbb{Z}_q[X]/(X^n - X^{n/2} + 1)$  for  $n = 2^a \cdot 3^b$  and prime number  $q$ . Boldface lower-case letters represent elements in  $R$  or  $R_q$ , and non-boldface lower-case letters represent elements in  $\mathbb{Z}$  and  $\mathbb{Z}_q$ .

**Modular Reductions.** For an integer  $\alpha$ , we let  $r' = r \bmod^\pm \alpha$  to be the unique integer  $r' \in (-\alpha/2, \alpha/2]$  such that  $r' \equiv r \bmod \alpha$ . Similarly, we let  $r' = r \bmod^+ \alpha$  to be the unique integer  $r' \in [0, \alpha)$ . For an element  $\mathbf{r} = r_0 + r_1X + \dots + r_{p-1}X^{p-1} \in R$ , we let  $\mathbf{r}' = \mathbf{r} \bmod^\pm \alpha$  (resp.  $\mathbf{r}' = \mathbf{r} \bmod^+ \alpha$ ) to be the unique element in  $R$  such that  $\mathbf{r}' = r'_0 + r'_1X + \dots + r'_{p-1}X^{p-1}$  and  $r'_i = r_i \bmod^\pm \alpha$  (resp.  $r'_i = r_i \bmod^+ \alpha$ ) for all  $i$ . When we do not require exact representation, we write  $r \bmod \alpha$  or  $\mathbf{r} \bmod \alpha$ .

**Sizes of elements.** For  $w \in \mathbb{Z}_q$ , we let  $\|w\|_\infty := |w \bmod^\pm q|$ . We also define  $l_\infty$  and  $l_2$  norm of  $\mathbf{w} = w_0 + w_1X + \dots + w_{p-1}X^{p-1} \in R$  as

$$\|\mathbf{w}\|_\infty := \max_i \|w_i\|_\infty, \quad \|\mathbf{w}\|_2 := \sqrt{\|w_0\|_\infty^2 + \dots + \|w_{p-1}\|_\infty^2},$$

respectively. We write  $S_\eta$  to denote the set of elements  $\mathbf{w} \in R$  that satisfy  $\|\mathbf{w}\|_\infty \leq \eta$ . We let  $\tilde{S}_\eta := \{\mathbf{w} \bmod^\pm 2\eta : \mathbf{w} \in R\}$ . One can see that  $\tilde{S}_\eta \subset S_\eta$ , but  $\tilde{S}_\eta$  does not include the elements with at least one  $-\eta$  coefficient.

**A New SampleInBall Algorithm.** We use multiple hashing algorithms that map strings in  $\{0, 1\}^*$  to random elements in desired domains such as  $S_\eta$  and  $R_q$ . **SampleInBall** algorithm maps a random seed  $\rho \in \{0, 1\}^{256}$  to an element of  $B_\tau$ , the subset of  $S_1$  consists of elements that have total  $\tau$  nonzero coefficients in  $\{-1, 0, 1\}$ . We propose a new **SampleInBall** algorithm using our ring structure for NCC-Sign Non-cyclotomic as follows: the challenge polynomial can be chosen in the following two ways

- choose a single polynomial  $\mathbf{c} \in R$  having  $\tau$  non-zero coefficients,
- choose two polynomials  $\mathbf{c}_i \in R$  having  $\tau_i$  non-zero coefficients for  $i = 1, 2$  and combine them such that  $\mathbf{c} = \mathbf{c}_2 + X^{p_2}\mathbf{c}_1$ . Note that  $\mathbf{c}_i$  is a degree- $(p_i - 1)$  polynomial.

It is enough to specify the method of choosing polynomial having fixed number of non-zero coefficients. Basically, we follow [20, 34]. High-level description is described in Algorithm 2.1. More specifically, Step 3 and 4 in Algorithm 2.1 can be done in the following way from the 256-bit hash seed  $\rho$ . We use SHAKE-256 to obtain a stream of random bytes of variable length from the seed  $\rho$ . The first  $\tau$  bits in the first 8 bytes of this random stream are  $\tau$  random sign bits  $s_i \in \{0, 1\}$ ,  $i = 0, \dots, \tau - 1$ , required in Step 4. The remaining  $64 - \tau$  bits are

discarded. For the random  $j$  required in Step 3, we use next 10 or 11 bits from the next two bytes in the stream and interpret it as a single number less than  $2^{10}$  or  $2^{11}$  depending on  $p$ . When this number is less than or equal to  $i$ , we use it as  $j$ . If not, we use next two bytes in the stream to choose  $j$ . Lastly, for the case of two polynomials, we use another SHAKE-256 to obtain 512-bits from the seed  $\rho$ . Then the first 256-bits are used as a seed for  $\mathbf{c}_1$  while the second 256-bits are used as a seed for  $\mathbf{c}_2$ . From the seeds, the needed randomness can be extracted as is described in Algorithm 2.1. We will analyze the probability of the rejection in **Sign** algorithm using the proposed **SampleInBall** in §3.3. For the case of trinomial, the **SampleInBall** algorithm is the same as Dilithium [20, 34].

---

**Algorithm 1**  $\text{SampleInBall}_{p,\tau}(\rho)$ .

Create a random  $p$ -element array with  $\tau$   $\pm 1$ 's and  $p - \tau$  0's. Use the input seed  $\rho$  (and an XOF) to generate the randomness needed in Step 3 and 4.

---

```

1: Initialize  $\mathbf{c} = c_0 c_1 \dots c_{p-1} = 00 \dots 0$ 
2: for  $i := p - \tau$  to  $p - 1$  do
3:    $j \leftarrow \{0, 1, \dots, i\}$ 
4:    $s \leftarrow \{0, 1\}$ 
5:    $c_i := c_j$ 
6:    $c_j := (-1)^s$ 
7: end for
8: return  $\mathbf{c}$ 

```

---

**Algorithm 2**  $\text{Decompose}_q(r, \alpha)$ 

---

```

1:  $r := r \bmod^+ q$ 
2:  $r_0 := r \bmod^\pm \alpha$ 
3: if  $r - r_0 = q - 1$  then
4:    $r_1 := 0$ 
5:    $r_0 := r_0 - 1$ 
6: else
7:    $r_1 := (r - r_0)/\alpha$ 
8: end if
9: return  $(r_1, r_0)$ 

```

---

**Algorithm 3**  $\text{UseHint}_q(h, r, \alpha)$ 

---

```

1:  $m := (q - 1)/\alpha$ 
2:  $(r_1, r_0) := \text{Decompose}_q(r, \alpha)$ 
3: if  $h = 1$  and  $r_0 > 0$  then
4:   return  $(r_1 + 1) \bmod^+ m$ 
5: end if
6: if  $h = 1$  and  $r_0 \leq 0$  then
7:   return  $(r_1 - 1) \bmod^+ m$ 
8: end if
9: return  $r_1$ 

```

---

**Algorithm 4**  $\text{Power2Round}_q(r, d)$ 

---

```

1:  $r := r \bmod^+ q$ 
2:  $r_0 := r \bmod^\pm 2^d$ 
3: return  $((r - r_0)/2^d, r_0)$ 

```

---

**Algorithm 5**  $\text{HighBits}_q(r, \alpha)$ 

---

```

1:  $(r_1, r_0) := \text{Decompose}_q(r, \alpha)$ 
2: return  $r_1$ 

```

---

**Algorithm 6**  $\text{LowBits}_q(r, \alpha)$ 

---

```

1:  $(r_1, r_0) := \text{Decompose}_q(r, \alpha)$ 
2: return  $r_0$ 

```

---

**Algorithm 7**  $\text{MakeHint}_q(z, r, \alpha)$ 

---

```

1:  $r_1 := \text{HighBits}_q(r, \alpha)$ 
2:  $v_1 := \text{HighBits}_q(r + z, \alpha)$ 
3: return  $\llbracket r_1 \neq v_1 \rrbracket$ 

```

---

**High/Low Order Bits and Hints.** We use several algorithms, Algorithm 2.1-2.1, that extract higher/lower bits of an input, and the other algorithms that help to correctly produce higher bits of a summation  $r + z \in \mathbb{Z}_q$  when  $r \in \mathbb{Z}_q$  and  $z \in \mathbb{Z}_q$  is small. The algorithms can be extended to use inputs in  $R_q$  (except for  $d$  and  $\alpha$ ) by applying the algorithm to each coefficient.

**Other Functions.**  $\text{ExpandA}$ ,  $\text{ExpandS}$  and  $\text{ExpandMask}$  maps random seeds to  $\mathbf{a} \in R_q$ ,  $(\mathbf{s}_1, \mathbf{s}_2) \in S_\eta \times S_\eta$ , and  $\mathbf{y} \in \tilde{S}_\eta$ , respectively. We instantiate function  $H$  as the extendable-output function (XOF) SHAKE-256.

## 2.2 Specification of NCC-Sign

The  $\text{KeyGen}$ ,  $\text{Sign}$  and  $\text{Verify}$  algorithms of NCC-Sign are presented in Algorithm 8, 9, and 10, respectively.

**Algorithm 8** KeyGen

---

```

1:  $(\zeta, \zeta') \leftarrow \{0, 1\}^{256} \times \{0, 1\}^{256}$ 
2:  $(\xi_1, \xi_2, K) \in \{0, 1\}^{256} \times \{0, 1\}^{256} \times \{0, 1\}^{256} := H(\zeta')$ 
3:  $\mathbf{a} \in R_q := \text{ExpandA}(\zeta)$  (Trinomial version:  $\hat{\mathbf{a}}(\neq 0) \in T_q := \text{ExpandA}(\zeta)$ )
4:  $(\mathbf{s}_1, \mathbf{s}_2) \in S_\eta \times S_\eta := \text{ExpandS}(\xi_1, \xi_2)$ 
5:  $\mathbf{t} := \mathbf{a}\mathbf{s}_1 + \mathbf{s}_2$  (trinomial version:  $\mathbf{t} := \text{INTT}(\hat{\mathbf{a}} \circ \text{NTT}(\mathbf{s}_1)) + \mathbf{s}_2$ )
6:  $(\mathbf{t}_1, \mathbf{t}_0) := \text{Power2Round}_q(\mathbf{t}, d)$ 
7:  $ph \in \{0, 1\}^{256} := H(\zeta \parallel \mathbf{t}_1)$ 
8: return  $(pk = (\zeta, \mathbf{t}_1), sk = (\zeta, ph, K, \mathbf{s}_1, \mathbf{s}_2, \mathbf{t}_0))$ 

```

---

**Algorithm 9** Sign( $sk, M$ )

---

```

1:  $\mathbf{a} \in R_q := \text{ExpandA}(\zeta)$  (Trinomial version:  $\hat{\mathbf{a}} \in T_q := \text{ExpandA}(\zeta)$ )
2:  $\mu \in \{0, 1\}^{512} := H(ph \parallel M)$ 
3:  $\kappa := 0, (\mathbf{z}, \mathbf{h}) := \perp$ 
4:  $\rho \in \{0, 1\}^{512} := H(K \parallel \mu)$  (or  $\rho \leftarrow \{0, 1\}^{512}$  for randomized signing)
5: while  $(\mathbf{z}, \mathbf{h}) = \perp$  do
6:    $\mathbf{y} \in \tilde{S}_{\gamma_1} := \text{ExpandMask}(\rho, \kappa)$ 
7:    $\mathbf{w} := \mathbf{a}\mathbf{y}$  (Trinomial version:  $\mathbf{w} := \text{INTT}(\hat{\mathbf{a}} \circ \text{NTT}(\mathbf{y}))$ )
8:    $\mathbf{w}_1 := \text{HighBits}_q(\mathbf{w}, 2\gamma_2)$ 
9:    $\tilde{c} \in \{0, 1\}^{256} := H(\mu \parallel \mathbf{w}_1)$ 
10:   $\mathbf{c} \in B_\tau := \text{SampleInBall}_{p, \tau}(\tilde{c})$  (Trinomial version additionally stores  $\hat{\mathbf{c}} := \text{NTT}(\mathbf{c})$ )
11:   $\mathbf{z} := \mathbf{y} + \mathbf{c}\mathbf{s}_1$  (Trinomial version:  $\mathbf{z} := \mathbf{y} + \text{INTT}(\hat{\mathbf{c}} \circ \text{NTT}(\mathbf{s}_1))$ )
12:   $\mathbf{r}_0 := \text{LowBits}_q(\mathbf{w} - \mathbf{c}\mathbf{s}_2, 2\gamma_2)$  (Trinomial version performs  $\text{INTT}(\hat{\mathbf{c}} \circ \text{NTT}(\mathbf{s}_2))$  to compute  $\mathbf{c}\mathbf{s}_2$ )
13:  if  $\|\mathbf{z}\|_\infty \geq \gamma_1 - \beta$  or  $\|\mathbf{r}_0\|_\infty \geq \gamma_2 - \beta$  then
14:     $(\mathbf{z}, \mathbf{h}) := \perp$ 
15:  else
16:     $\mathbf{h} := \text{MakeHint}_q(-\mathbf{c}\mathbf{t}_0, \mathbf{w} - \mathbf{c}\mathbf{s}_2 + \mathbf{c}\mathbf{t}_0, 2\gamma_2)$  (Trinomial version performs  $\text{INTT}(\hat{\mathbf{c}} \circ \text{NTT}(\mathbf{t}_0))$  to compute  $\mathbf{c}\mathbf{t}_0$ )
17:    if  $\|\mathbf{c}\mathbf{t}_0\|_\infty \geq \gamma_2$  or the # of 1's in  $\mathbf{h}$  is greater than  $\omega$  then
18:       $(\mathbf{z}, \mathbf{h}) := \perp$ 
19:    end if
20:     $\kappa := \kappa + 1$ 
21:  end if
22: end while
23: return  $\sigma = (\tilde{c}, \mathbf{z}, \mathbf{h})$ 

```

---

**Algorithm 10**  $\text{Verify}(pk, M, \sigma = (\tilde{c}, \mathbf{z}, \mathbf{h}))$ 

- 
- 1:  $\mathbf{a} \in R_q := \text{ExpandA}(\zeta)$  (Trinomial version:  $\hat{\mathbf{a}} \in T_q := \text{ExpandA}(\zeta)$ )
  - 2:  $\mu \in \{0, 1\}^{512} := H(H(\zeta \parallel \mathbf{t}_1) \parallel M)$
  - 3:  $\mathbf{c} := \text{SampleInBall}(\tilde{c})$  (Trinomial version additionally stores  $\hat{\mathbf{c}} := \text{NTT}(\mathbf{c})$ )
  - 4:  $\mathbf{w}'_1 := \text{UseHint}_q(\mathbf{h}, \mathbf{a}\mathbf{z} - \mathbf{c}\mathbf{t}_1 \cdot 2^d, 2\gamma_2)$  (Trinomial version performs  $\text{INTT}(\hat{\mathbf{a}} \circ \text{NTT}(\mathbf{z}))$  and  $\text{INTT}(\hat{\mathbf{c}} \circ \text{NTT}(2^d \cdot \mathbf{t}_1))$  to compute  $\mathbf{a}\mathbf{z}$  and  $\mathbf{c}\mathbf{t}_1 \cdot 2^d$ , respectively)
  - 5: **return**  $\llbracket \|\mathbf{z}\|_\infty < \gamma_1 - \beta \rrbracket$  **and**  $\llbracket \tilde{c} = H(\mu \parallel \mathbf{w}'_1) \rrbracket$  **and**  $\llbracket \# \text{ of 1's in } \mathbf{h} \text{ is } \leq \omega \rrbracket$
- 

We offer both deterministic and randomized versions of the algorithm **Sign**. For randomized version, the procedure for generating  $\rho$  is replaced by random sampling from  $\{0, 1\}^{512}$ , whereas deterministic version uses collision-resistant hash function to digest a message  $M$  into  $\mu$  using the hash value of the public key  $pk$ , then uses a secret key  $sk$  and  $\mu$  as an input of  $H$  to safely generate  $\rho$ . We use two separate seeds,  $\zeta$  and  $\zeta'$ , to generate a public key  $\mathbf{a}$  and a secret key  $(\mathbf{s}_1, \mathbf{s}_2, K)$ , respectively.

We let  $T_q$  to be the domain of NTT representations, and  $\circ$  to be the coordinate-wise multiplication in  $T_q$ .  $\text{NTT}$  and  $\text{INTT}$  are NTT and inverse NTT operations, respectively. We note that a random string sampled from  $\text{ExpandA}$  can be interpreted as a random element in  $T_q$  as well. Therefore, we can write  $\hat{\mathbf{a}} \in T_q := \text{ExpandA}(\zeta)$  to sample the NTT representation of a random element  $\mathbf{a} \in R_q$ . The security proof of NCC-Sign in §3.1 requires the invertibility of  $\mathbf{a}$ . In fact, in Non-cyclotomic version,  $\mathbf{a}$  is always invertible, but in Trinomial version, its invertibility must be checked. For this,  $\text{ExpandA}$  iteratively samples  $\hat{\mathbf{a}}$  until none of the coefficients of  $\hat{\mathbf{a}}$  is zero, which makes  $\mathbf{a}$  invertible in step 3 of Algorithm 8.

### 3 Security Analysis and Parameter Selections

#### 3.1 Existential Unforgeability

For security proof, we use the following hardness assumptions.

**Definition 1 (Ring-LWE Problem).** *Let  $q$  be a positive integer. For a probability distribution  $\chi$  over  $R_q$ , sample  $\mathbf{a} \xleftarrow{\$} R_q$  and a vector  $\mathbf{s}_1, \mathbf{s}_2 \leftarrow \chi$ , and output  $(\mathbf{a}, \mathbf{a}\mathbf{s}_1 + \mathbf{s}_2)$ .*

**Definition 2 (Decision Ring-LWE Problem).** *Given a pair  $(\mathbf{a}, \mathbf{t})$  decide, with non-negligible advantage, whether it came from the RLWE distribution or it was generated uniformly at random from  $R_q \times R_q$ . The advantage of the adversary  $\mathcal{A}$  in solving decisional RLWE problem over the ring  $R_q$  is*

$$\text{Adv}_{\chi}^{\text{Ring-LWE}}(\mathcal{A}) := \left| \Pr[b = 1 \mid \mathbf{a}, \mathbf{t} \xleftarrow{\$} R_q; b \leftarrow \mathcal{A}(\mathbf{a}, \mathbf{t})] - \Pr[b = 1 \mid \mathbf{a} \xleftarrow{\$} R_q, \mathbf{s}_1, \mathbf{s}_2 \leftarrow \chi; b \leftarrow \mathcal{A}(\mathbf{a}, \mathbf{a}\mathbf{s}_1 + \mathbf{s}_2)] \right|.$$

We say RLWE is hard when the above advantage is negligible for all (quantum) probabilistic polynomial-time algorithm  $\mathcal{A}$ .

**Definition 3 (Ring-SIS Problem).** *The advantage of the adversary  $\mathcal{A}$  to solve RSIS problem over the ring  $R_q$  is*

$$\text{Adv}_{l,\gamma}^{\text{Ring-SIS}}(\mathcal{A}) := \Pr \left[ 0 < \|\vec{y}\|_\infty \leq \gamma \wedge [\mathbf{a}_1 \dots \mathbf{a}_l \ 1] \cdot \vec{y} = 0 \mid \mathbf{a}_1 \dots, \mathbf{a}_l \xleftarrow{\$} R_q; \vec{y} \leftarrow \mathcal{A}(\mathbf{a}_1, \dots, \mathbf{a}_l) \right].$$

**Definition 4 (SelfTargetRSIS Problem).** *For the cryptographic hash function  $H$ , the advantage of  $\mathcal{A}$  to solve SelfTargetRSIS problem  $\text{Adv}_{H,\gamma}^{\text{SelfTargetRSIS}}(\mathcal{A})$  is defined as*

$$\Pr \left[ \begin{array}{c} 0 \leq \|\vec{y}\|_\infty \leq \gamma \wedge \\ H(\mu \| [\mathbf{a}_1 \ \mathbf{a}_2 \ 1] \cdot \vec{y}) = \mathbf{c} \end{array} \mid \mathbf{a}_1, \mathbf{a}_2 \xleftarrow{\$} R_q; \left( \vec{y} := \begin{bmatrix} \mathbf{r}_1 \\ \mathbf{c} \\ \mathbf{r}_2 \end{bmatrix}, \mu \right) \leftarrow \mathcal{A}^{H(\cdot)}(\mathbf{a}_1, \mathbf{a}_2) \right].$$

We note that there is a classical reduction from RSIS to SelfTargetRSIS [20, 34].

For security analysis of our scheme, we need the following lemmas in [34, 20].

**Lemma 1 ([20, 34]).** *Suppose that  $q$  and  $\alpha$  are positive integers satisfying  $q > 2\alpha$ ,  $q \equiv 1 \pmod{\alpha}$  and  $\alpha$  is even. Let  $\mathbf{r}$  and  $\mathbf{z}$  be elements of  $R_q$  where  $\|\mathbf{z}\|_\infty \leq \alpha/2$ , and let  $\mathbf{h}, \mathbf{h}'$  be vectors of bits (polynomials in  $R_q$  where coefficients are 0 or 1). Then the  $\text{HighBits}_q$ ,  $\text{MakeHint}_q$ , and  $\text{UseHint}_q$  algorithms satisfy the following properties:*

1.  $\text{UseHint}_q(\text{MakeHint}_q(\mathbf{z}, \mathbf{r}, \alpha), \mathbf{r}, \alpha) = \text{HighBits}_q(\mathbf{r} + \mathbf{z}, \alpha)$ .
2. Let  $\mathbf{v}_1 = \text{UseHint}_q(\mathbf{h}, \mathbf{r}, \alpha)$ . Then  $\|\mathbf{r} - \mathbf{v}_1 \cdot \alpha\|_\infty \leq \alpha + 1$ . Furthermore, if the number of 1's in  $\mathbf{h}$  is  $\omega$ , then all except at most  $\omega$  coefficients of  $\mathbf{r} - \mathbf{v}_1 \cdot \alpha$  will have magnitude of at most  $\alpha/2$  after centered reduction modulo  $q$ .
3. For any  $\mathbf{h}, \mathbf{h}'$ , if  $\text{UseHint}_q(\mathbf{h}, \mathbf{r}, \alpha) = \text{UseHint}_q(\mathbf{h}', \mathbf{r}, \alpha)$ , then  $\mathbf{h} = \mathbf{h}'$ .

**Lemma 2 ([20, 34]).** *If  $\|\mathbf{s}\|_\infty \leq \beta$  and  $\|\text{LowBits}_q(\mathbf{r}, \alpha)\|_\infty < \alpha/2 - \beta$ , then*

$$\text{HighBits}_q(\mathbf{r}, \alpha) = \text{HighBits}_q(\mathbf{r} + \mathbf{s}, \alpha).$$

**Sketch of Security Proofs.** For existential unforgeability against chosen-message attacks (UF-CMA), existential unforgeability against no-message attacks (UF-NMA) is sufficient if the underlying identification scheme is accepting honest-verifier zero-knowledge (acHVZK) [7]. The security of Dilithium is analyzed in [31] where Fiat-Shamir signatures are analyzed and it is shown that deterministic UF-NMA secure signature schemes are also UF-CMA-secure in the QROM. However, the gap in CMA to NMA reduction is found and fixed in [7, 19]. The gap lies in the fact that non-accepting transcripts disturbs the distribution of random oracle answers towards accepting transcripts. To fix this gap, [19] considers HVZK simulator for reprogramming accepted and rejected transcripts and [7] uses additional hybrid step that removes rejected transcripts. In

the end, with worse bound, [7, 19] provide the security proof of Dilithium which need larger commitment min-entropy.

Since NCC-Sign is a ring-version of Dilithium over the non-cyclotomic ring and the cyclotomic trinomial ring, the security proof of Dilithium can be applied to NCC-Sign as it is. What we have to do is to check the bound when two polynomials are multiplied and when  $k = l = 1$  is applied. NCC-Sign has slightly worse bound than Dilithium because of the coefficient growth when two polynomials are multiplied. We sketch that NCC-Sign achieves acHVZK and UF-NMA in (Q)ROM. We assume that a public key is given without the compression. Proving security in this case also shows the security when compression is used. We let  $H$  to be a random oracle that maps its input to an element in  $B_\tau$ .

*UF-NMA security.* In order to prove UF-NMA of our scheme based on RLWE and SelfTargetRSIS assumptions, firstly using RLWE assumption, we replace the public key by random elements of  $R_q$ ,  $(\mathbf{a}, \mathbf{t})$ . Then, the adversary  $\mathcal{A}$  receives  $(\mathbf{a}, \mathbf{t})$  and needs to output valid message/signature pair  $M$  and  $(\mathbf{z}, \mathbf{h}, \mathbf{c})$  such that

$$\|\mathbf{z}\|_\infty < \gamma_1 - \beta, H(\mu \| \text{UseHint}_q(\mathbf{h}, \mathbf{az} - \mathbf{ct}_1 \cdot 2^d, 2\gamma_2)) = \mathbf{c},$$

and the number of 1's in  $\mathbf{h}$  is less than  $\omega$ . Lemma 1 implies

$$2\gamma_2 \cdot \text{UseHint}_q(\mathbf{h}, \mathbf{az} - \mathbf{ct}_1 \cdot 2^d, 2\gamma_2) = \mathbf{az} - \mathbf{ct}_1 \cdot 2^d + \mathbf{v},$$

where  $\|\mathbf{v}\|_\infty \leq 2\gamma_2 + 1$ . Let  $\mathbf{t} = \mathbf{t}_1 \cdot 2^d + \mathbf{t}_0$  where  $\|\mathbf{t}_0\|_\infty \leq 2^{d-1}$ . Then

$$\mathbf{az} - \mathbf{ct}_1 \cdot 2^d + \mathbf{v} = \mathbf{az} - \mathbf{c}(\mathbf{t} - \mathbf{t}_0) + \mathbf{v} = \mathbf{az} - \mathbf{ct} + (\mathbf{ct}_0 + \mathbf{v}) = \mathbf{az} - \mathbf{ct} + \mathbf{v}',$$

where  $\|\mathbf{v}'\|_\infty \leq 2\tau 2^{d-1} + 2\gamma_2 + 1$ . It follows that using adversary, we find  $\mathbf{z}, \mathbf{c}, \mathbf{v}', M$  such that  $\|\mathbf{z}\|_\infty < \gamma_1 - \beta$ ,  $\|\mathbf{c}\|_\infty = 1$ ,  $\|\mathbf{v}'\|_\infty \leq 2\tau \cdot 2^{d-1} + 2\gamma_2 + 1$ ,  $M \in \{0, 1\}^*$ , such that

$$H(\mu \| \frac{1}{2\gamma_2} [\mathbf{a} - \mathbf{t} \ 1] \cdot \begin{bmatrix} \mathbf{z} \\ \mathbf{c} \\ \mathbf{v}' \end{bmatrix}) = \mathbf{c}.$$

Let  $H(\mu \| \mathbf{x}) = H'(\mu \| 2\gamma_2 \cdot \mathbf{x})$ . Then  $H'(\mu \| [\mathbf{a} - \mathbf{t} \ 1] \cdot \begin{bmatrix} \mathbf{z} \\ \mathbf{c} \\ \mathbf{v}' \end{bmatrix}) = \mathbf{c}$  and this solves the SelfTargetRSIS problem with  $\gamma = \max\{\gamma_1 - \beta, 2\tau \cdot 2^{d-1} + 2\gamma_2 + 1\}$ .

*Zero-knowledgeness.* Now we prove that our scheme is acHVZK. Assume that public key is  $\mathbf{t}$  (rather than  $\mathbf{t}_1$ ). We note that  $\mathbf{t}_0$  is used in simulation. It is clear that if our scheme is zero-knowledge with  $\mathbf{t}$  then it is zero-knowledge with  $\mathbf{t}_1$ . Let  $\mathbf{w} = \mathbf{ay}$  and  $\mathbf{z} = \mathbf{y} + \mathbf{cs}_1$ . Then  $\mathbf{w} - \mathbf{cs}_2 = \mathbf{ay} - \mathbf{cs}_2 = \mathbf{az} - \mathbf{ct}$  since

$$\mathbf{az} - \mathbf{ct} = \mathbf{a}(\mathbf{y} + \mathbf{cs}_1) - \mathbf{ct} = \mathbf{ay} + \mathbf{acs}_1 - \mathbf{ct} = \mathbf{ay} - \mathbf{c}(\mathbf{t} - \mathbf{as}_1) = \mathbf{w} - \mathbf{cs}_2.$$

Now,  $\Pr[\mathbf{z}, \mathbf{c}] = \Pr[\mathbf{c}] \Pr[\mathbf{y} = \mathbf{z} - \mathbf{c}\mathbf{s}_1 \mid \mathbf{c}]$  where  $\|\mathbf{z}\|_\infty \leq \gamma_1 - \beta$ . If  $\|\mathbf{c}\mathbf{s}_i\|_\infty \leq \beta$ , then  $\|\mathbf{z} - \mathbf{c}\mathbf{s}_i\|_\infty \leq \gamma_1 - 1$ . Since  $\mathbf{y}$  is chosen uniformly random from  $\tilde{S}_{\gamma_1}$ , the probability is the same for all  $(\mathbf{z}, \mathbf{c})$ . For the simulation, we pick uniformly random

$$(\mathbf{z}, \mathbf{c}) \in S_{\gamma_1 - \beta - 1} \times B_\tau$$

and check  $\|\mathbf{r}_0\|_\infty = \|\text{LowBits}_q(\mathbf{w} - \mathbf{c}\mathbf{s}_2, 2\gamma_2)\|_\infty = \|\text{LowBits}_q(\mathbf{a}\mathbf{z} - \mathbf{c}\mathbf{t}, 2\gamma_2)\|_\infty \leq \gamma_2 - \beta$ . Since  $\mathbf{h}$  can be constructed when  $(\mathbf{z}, \mathbf{c})$  is sampled, and such simulation's output is indistinguishable from the honestly generated *accepting* transcript, our underlying identification scheme is acHVZK.

At last, we compute the commitment min-entropy in the security proof of NCC-Sign, which requires the invertibility of  $\mathbf{a}$ . When  $\phi = X^p - X - 1$ ,  $\mathbf{a}$  is always invertible, but it is not in the case that  $\phi = X^n - X^{n/2} + 1$ . The key generation in Algorithm 8 checks its invertibility in NCC-Sign Trinomial.

Commitment min-entropy. Let  $R = \mathbb{Z}[X]/\phi$  and  $R_q = \mathbb{Z}_q[X]/\phi$ . We consider the min-entropy of the commitment in the underlying sigma protocol. First, we assume that  $\mathbf{a}$  is invertible. Now, for every possible  $\mathbf{w}_1$ , we need to compute the probability that  $\text{HighBits}_q(\mathbf{a}\mathbf{y}, 2\gamma_2)$  equals  $\mathbf{w}_1$  when  $y$  is uniformly sampled from  $\tilde{S}_{\gamma_1}$  for  $\mathbf{a}, \mathbf{y} \in R_q$  where  $|\tilde{S}_{\gamma_1}| = (2\gamma_1)^n$ . To compute the probability, we consider the set  $T_{\mathbf{w}_1} = \{\mathbf{w} \in R_q \mid \text{HighBits}_q(\mathbf{w}, 2\gamma_2) = \mathbf{w}_1\}$ . Note that  $|T_{\mathbf{w}_1}| \approx (2\gamma_2)^n$ . We have  $\Pr_{y \leftarrow \tilde{S}_{\gamma_1}}[\text{HighBits}_q(\mathbf{a}\mathbf{y}, 2\gamma_2) = \mathbf{w}_1] = \Pr_{y \leftarrow \tilde{S}_{\gamma_1}}[\mathbf{a}\mathbf{y} = \mathbf{w}, \mathbf{w} \in T_{\mathbf{w}_1}] = \Pr_{y \leftarrow \tilde{S}_{\gamma_1}}[\mathbf{y} = \mathbf{w}\mathbf{a}^{-1}, \mathbf{w} \in T_{\mathbf{w}_1}] \leq \frac{|T_{\mathbf{w}_1}|}{|\tilde{S}_{\gamma_1}|} \approx \left(\frac{\gamma_2}{\gamma_1}\right)^n$ , and the minimum entropy is about  $n/2$  to  $n$  depending on the parameter set. This minimum entropy is larger than 500 already for the our parameter at the security level 1 in §3.3.

### 3.2 Security Estimates for RLWE and RSIS

We follow the core-SVP method: BKZ- $b$  calls the SVP oracle of dimension  $b$  which costs in time  $\approx 2^{0.292b}$ . For a given basis  $(\mathbf{c}_1, \dots, \mathbf{c}_n)$  as input,  $\mathbf{c}_k(i)$  is a projection of  $\mathbf{c}_k$  orthogonally to the vectors  $(\mathbf{c}_1, \dots, \mathbf{c}_i)$ , let  $\ell_i = \log_2 \|\mathbf{c}_i(i-1)\|$ . BKZ preserves the determinant of the  $\mathbf{c}_i$ 's, and the sum of the  $\ell_i$ s remains constant. After small number of SVP calls inside the BKZ algorithm, we expect the local slope of the  $\ell_i$ s converges to

$$\text{slope}(b) = \frac{1}{b-1} \log_2 \left( \frac{b}{2\pi e} (\pi \cdot b)^{1/b} \right).$$

After the BKZ reduction,  $\ell_i$ s are of the following forms:

- The first  $\ell_i$ s are constant equal to  $\log_2 q$  (possibly empty).
- Then they decrease linearly, with slope  $\text{slope}(b)$ .
- The last  $\ell_i$ s are constant equal to 0 (possibly empty).

Throughout this section, we write  $\text{vec}(\mathbf{x}) = [x_0, x_1, \dots, x_{p-1}]^T$  when  $\mathbf{x} = x_0 + x_1X + \dots + x_{p-1}X^{p-1} \in R_q$ , and  $\text{rot}(\mathbf{x})$  is a matrix whose  $k$ -th column vector

is  $\text{vec}(X^{k-1} \cdot \mathbf{x})$ . Also,  $\text{rot}(\mathbf{x})_{[1:m]}$  is a  $m \times p$  matrix consisting of first  $m$  rows of a matrix  $\text{rot}(\mathbf{x})$ .

**Solving RLWE.** Any RLWE instance over  $R$  can be viewed as a LWE instance. Let  $(\mathbf{a}, \mathbf{b}) \in R_q^2$  be a RLWE instance over  $R_q$ , where  $\mathbf{b} = \mathbf{a} \cdot \mathbf{s}_1 + \mathbf{s}_2$ . Main lattice attack is a primal attack which finds short vectors in the following lattice  $L$  of dimension  $d = p + m + 1$  and determinant  $q^m$  which has the

solution vector  $(\text{vec}(\mathbf{s}_2), \text{vec}(\mathbf{s}_1), 1)$ :  $L = \begin{bmatrix} qI_m & -\text{rot}(\mathbf{a})_{[1:m]} & \mathbf{b} \\ & I_p & 0 \\ & & 1 \end{bmatrix}$ . It is known that

one can expect to find the solution if  $2^{\ell_{d-b}}$  is greater than the expected norm of  $(\text{vec}(\mathbf{s}_2), \text{vec}(\mathbf{s}_1), 1)$  after projection orthogonally to the first  $d - b$  vectors, which is  $\varsigma\sqrt{b}$ , where  $\varsigma$  is a standard deviation of coordinates of  $\mathbf{s}_1, \mathbf{s}_2$ . When it is uniform on  $[-1, 0, 1]$ , it is  $\sqrt{2/3} \approx 0.816$ . For  $[-2, -1, 0, 1, 2]$ , it is about 1.414 and for  $[-4, -3, -2, -1, 0, 1, 2, 3, 4]$ , it is about 2.582. We also assume that the number of SVP calls inside BKZ is larger than  $d$  which equals to  $p + m + 1$ .

**Solving RSIS and SelfTargetRSIS.** For the RSIS and SelfTargetRSIS problem, we consider those problems as a RSIS problem. For the RSIS problem, given uniformly sampled polynomials  $\mathbf{a}_i \in R_q$ ,  $i = 1, \dots, k$ , it is required to find small polynomials  $\mathbf{y}_i$ ,  $i = 0, \dots, k$ , s.t.  $\mathbf{y}_0 + \sum_{i=1}^k \mathbf{y}_i \mathbf{a}_i = 0$  and  $\|\mathbf{y}_i\|_\infty \leq \gamma$ . Using rotation matrix, the RSIS problem can be solved by lattice reduction algorithms finding short vectors in the following lattice basis of determinant  $q^p$  which has the solution vector  $(-\text{vec}(\mathbf{y}_0), \text{vec}(\mathbf{y}_1), \dots, \text{vec}(\mathbf{y}_k))$ :

$$L = \begin{bmatrix} qI_p & \text{rot}(\mathbf{a}_1) & \dots & \text{rot}(\mathbf{a}_k) \\ & I & & \\ & & \ddots & \\ & & & I \end{bmatrix}.$$

To find the solution vector of the lattice, one uses the BKZ algorithm of block size  $b$  after choosing  $w$  columns among rotated vectors to obtain a lattice of dimension  $d = w + p$ . As is explained above, after the BKZ algorithm, one can obtain  $\ell_i$ s. Let  $i$  be the smallest index such that  $\ell_i$  is below  $\log_2 q$  and  $j$  be the largest index such that  $\ell_j$  is above 0. Then, from the BKZ algorithm, one obtains  $\sqrt{4/3}^b$  short vectors of length  $2^{\ell_i}$  after projection to the first  $i - 1$  vectors. Now we assume that our short vectors have coordinates that satisfy the followings:

- the first  $i - 1$  coordinates are uniform modulo  $q$ .
- the next  $j - i + 1$  coordinates have similar magnitude and sampled from Gaussian distribution of standard deviation  $\sigma$  where  $\sigma = 2^{\ell_i} / \sqrt{j - i + 1}$ .
- the last  $w - j$  coordinates are zeroes.

If those  $j$  coordinates are all have absolute values less than  $\gamma$ , then the vector is considered as a solution vector. Time complexity of the algorithm finding a SIS solution is the cost of BKZ- $b$  multiplied by the inverse of the success probability

of finding such vectors within the  $\sqrt{4/3}^b$  vectors. Similar to Dilithium, we also consider the forget  $q$  case. In this case, the lattice basis is first multiplied by some random unimodular matrices to remove the first  $q$ -vectors. Then the BKZ algorithm is applied and we assume that  $q$ -vectors are not found. The above analysis is applied in the same way to  $i = 1$ . As in the RLWE case, we assume that the cost of BKZ- $b$  is the cost of SVP $_b$  multiplied by the dimension  $d$ .

**Other Attacks.** There exist other attacks like algebraic attacks. However, we do not consider algebraic attacks since they usually need many samples. Our signature scheme only offer one RLWE sample, which translates to  $p$  LWE samples. Since hybrid attacks are especially suitable to sparse secret, we do not consider these attacks.

### 3.3 Parameter Selection for NCC-Sign

According to our security proof, NCC-Sign is secure as long as the following problems are hard:

- RLWE $_D$  where  $D$  is a uniform distribution over  $S_\eta$
- SelfTargetRSIS with  $k = 2, \zeta$  where  $\zeta = \max\{\gamma_1 - \beta, 2\gamma_2 + 1 + 2^d \cdot \tau\}$
- RSIS with  $k = 1, \zeta'$  where  $\zeta' = \max\{2(\gamma_1 - \beta), 4\gamma_2 + 2\}$

Classically, SelfTargetRSIS with  $\zeta$  can be reduced from RSIS with  $2\zeta$ . Thus for the concrete parameters, we consider RSIS with  $k = 2, 2\zeta$  instead of the SelfTargetRSIS problem for simplicity. Thus, we consider the following problems for the concrete parameters:

- RLWE $_D$  where  $D$  is a uniform distribution over  $S_\eta$
- RSIS with  $k = 2, \zeta = \max\{2(\gamma_1 - \beta), 4\gamma_2 + 2 + 2^{d+1} \cdot \tau\}$
- RSIS with  $k = 1, \zeta' = \max\{2(\gamma_1 - \beta), 4\gamma_2 + 2\}$

#### [NCC-Sign Non-cyclotomic]

We aim to choose conservative parameter sets whose classical Core-SVP estimates are exceed 128, 192, and 256 at the three security levels, respectively.

**Table 1.** Some inert primes  $q$  for a given  $p$

$p$	$q$
1021	8348477, 8339581, 8333113
1429	8380087, 8376649, 8333131, 8332559
1913	8361623, 8343469, 8334383

- We can find enough list of candidate inert primes for each prime  $p$ , and find suitable primes  $p$  and  $q$  in the list satisfying  $q \equiv 1 \pmod{2\gamma_2}$ . This condition is needed for the correct verification and  $q - 1$  needs to have small even divisor. In Table 1, we list some inert primes  $q$  for a given  $p$ . We choose suitable  $p$  and  $q$  such that the expected number of repetitions in the rejection samplings is not too large for efficiency.

- The first parameter sets using  $\eta = 2$  is given in Table 2, where their Core-SVP estimates are 135, 194, and 261 bits at the three security levels, respectively, and the LWE cost is higher than the SIS cost. We choose another parameter sets using  $\eta = 1$  given in Table 3 to balance the security of SIS and LWE problems, where the SIS cost is only slightly higher than the LWE cost.
- Actually, larger  $\eta$  makes the underlying LWE problem harder, at the cost of less efficient rejection sampling since  $\beta = 2\tau\eta$  in the expected number of the rejection sampling. In the second parameter set of  $\eta = 1$ , the expected numbers of repetitions in the rejection samplings are 1.58, 1.74, and 1.98 at the three security levels, respectively, which are reduced by half, compared to the first parameter sets.
- In the Tables, Exp. reps. represents the expected numbers of repetitions in rejection samplings. The expected numbers in the first parameter set is calculated by  $e^{(p_1\beta_2+p_2\beta_1)(1/\gamma_1+1/\gamma_2)}$  from the proposed `SampleInBall` algorithm which will be analyzed in the next paragraph. In Table 2, they are calculated by  $e^{n\beta(1/\gamma_1+1/\gamma_2)}$  as in Dilithium.
- We estimate cost of NCC-Sign parameters in the Core-SVP model. LWE and SIS security is estimated using the script from <https://github.com/pq-crystals/security-estimates>. LWE cost by the lattice estimator is calculated from <https://github.com/malb/lattice-estimator>.
- The use of  $\eta = 1$  means that the ternary secret and error are used. It is known that hybrid attacks are more effective to the ternary secret case. We provide cost analysis of the second parameter sets against the hybrid attacks. For security of the second parameter set against the hybrid attacks, we use the code published in [https://github.com/bencrsts/hybrid\\_attacks](https://github.com/bencrsts/hybrid_attacks), which uses hybrid-decoding and hybrid-dual attacks. In Table 3, the model ‘usvp’ means that solving unique shortest vector problem is the best estimated strategy.
- For quantum security, we utilize the simple estimation method that uses classical security estimate with BKZ block size  $b$ . For this, we assume that solving the shortest vector problem in a lattice of dimension  $b$  costs  $2^{0.292b}$  and  $2^{0.265b}$  for classical and quantum attackers, respectively. Additionally, we assume the square-root quantum attacker for the rest attack cost. Namely, we estimate the quantum cost from the classical cost:  $2^{a+0.292b}$  (classical) becomes  $2^{a/2+0.265b}$  (quantum).

**Table 2.** Parameter set of NCC-Sign Non-cyclotomic ( $\eta = 2$ ).

Parameter/Security Level	1 <sup>c</sup>	3 <sup>c</sup>	5 <sup>c</sup>

**Number of Repetitions.** We analyze the probability of the rejection in **Sign** algorithm using the proposed **SampleInBall**. We choose the challenge polynomial  $\mathbf{c} \in \mathcal{R}$  having  $\tau$  non-zero coefficients. For optimization, our optimized **SampleInBall** algorithm chooses  $\mathbf{c} \in R = \mathbb{Z}[X]/(X^p - X - 1)$  differently: choose two (or more) separate polynomials. Now, we calculate the probability that Step 12-13 pass in **Sign** algorithm and investigate optimization effects of our algorithm for the suggested parameter sets.

Let  $\kappa$  be a challenge entropy,  $p_1 = (p - 1)/2$ , and  $p_2 = (p + 1)/2$  with  $p_1 + p_2 = p$ . First, choose  $\tau_1, \tau_2$  such that

$$\log \binom{p_1}{\tau_1} + \tau_1 + \log \binom{p_2}{\tau_2} + \tau_2 > \kappa.$$

Then choose  $\mathbf{c} = \mathbf{c}_2 + X^{p_2}\mathbf{c}_1$ , where  $\mathbf{c}_i$  is a degree- $(p_i - 1)$  polynomial of coefficients in  $\{-1, 0, 1\}$  and the sum of absolute value of the coefficient is  $\tau_i$  for  $i = 1, 2$ . Now, consider the product  $\mathbf{c} \cdot \mathbf{s} \in R$ , where  $\mathbf{s}$  has also small coefficients whose absolute value is not greater than  $\eta$ .

Let  $\mathbf{t} = \mathbf{s} \cdot X^i$  and  $t_j$  be the  $j$ -th coefficient of  $\mathbf{t}$ . Then, for  $i = 0$ , it is clear that  $|t_j| \leq \eta$  for all  $j$ . For  $i = 1$ , it can be seen that  $|t_j| \leq \eta$  for all  $j$  except that  $|t_1| \leq 2\eta$ . For  $i = 2$ , it can also be seen that  $|t_j| \leq \eta$  for all  $j$  but  $j = 1, 2$  where  $|t_1|, |t_2| \leq 2\eta$ . Similarly, for  $\mathbf{t} = \mathbf{s} \cdot X^i$ , it can be seen that  $|t_j| \leq \eta$  for all  $j$  except  $j = 1, 2, \dots, i$ . Thus, for  $i < p_2$ ,  $|t_j| \leq \eta$  for  $j \geq p_2$  and  $|t_j| \leq 2\eta$  for  $j < p_2$ .

Now let  $\mathbf{t} = \mathbf{s} \cdot \mathbf{c}_2 \in R$  and  $t_j$  be the coefficient of  $\mathbf{t}$ . Since  $\mathbf{c}_2$  has a degree less than  $p_2$  and has only  $\tau_2$  non-zero coefficients, we know that  $|t_j| \leq \tau_2\eta$  for  $j \geq p_2$  and  $|t_j| \leq 2\tau_2\eta$  for  $j < p_2$ . Let  $\mathbf{u} = \mathbf{s} \cdot \mathbf{c} \in R$  and  $u_j$  be the coefficient of  $\mathbf{u}$ . Then it can be seen that  $|u_j| \leq (2\tau_1 + \tau_2)\eta$  for  $j \geq p_2$  and  $|u_j| \leq 2(\tau_1 + \tau_2)\eta$  for  $j < p_2$ . Let  $\beta_1 = 2(\tau_1 + \tau_2)\eta$  and  $\beta_2 = (2\tau_1 + \tau_2)\eta$ . Let  $\mathbf{z}$  be the signature and  $z_j$  be the coefficient of  $\mathbf{z}$ . Then in the signature generation, we can check  $|z_j| < \beta_1$  for  $j < p_2$  and  $|z_j| < \beta_2$  for  $j \geq p_2$  instead of  $|z_j| < \beta$ . Since  $\beta_2$  is smaller than  $\beta_1$  and  $\beta_1$  is only slightly larger than  $\beta$ , the rejection probability could become smaller. More concretely, the expected repetitions become

$$e^{(p_1\beta_2 + p_2\beta_1)(1/\gamma_1 + 1/\gamma_2)}$$

instead of  $e^{p\beta(1/\gamma_1 + 1/\gamma_2)}$ . In Table 4, we can see that this optimization offers speed-up ranging from 9% to 24%, depending on the two parameter sets. The numbers in parentheses of Exp. reps. are the expected numbers of repetitions calculated by  $e^{p\beta(1/\gamma_1 + 1/\gamma_2)}$  in [20, 34].

**Table 4.** Optimization effects for our parameter sets using new **SampleInBall**.

Parameter	$p$	$\tau$	$\kappa$	$p_1, p_2$	$\beta_1, \beta_2$	Exp. reps.	Speed-up

$3^c$	1607	32	254	803,804	132,98	2.7 (3.02)	1.11
$5^c$	2039	32	265	1019,1020	132,98	3.43 (3.95)	1.15

**[NCC-Sign Trinomial]**

NCC-Sign Trinomial uses the polynomial ring  $R_q = \mathbb{Z}_q[X]/(X^n - X^{n/2} + 1)$ , where  $\varphi(X) = X^n - X^{n/2} + 1$  is the  $m$ -th cyclotomic polynomial with  $m$  of the form  $m = 2^a \cdot 3^b$ ,  $a, b \geq 1$  and  $n = \varphi(m) = m/3$ . We aim to choose conservative parameter sets whose classical Core-SVP estimates are closest to or exceed 128, 192, and 256 at the three security levels, respectively. Depending on the complexity of the LWE problem and the SIS problem at the required security levels, we choose appropriate parameter sets so that the expected number of repetition in the rejection samplings is not too large.

- The degree of the polynomial has of the form  $2^a \cdot 3^b$  which allows to choose flexible parameters. Possible degrees of the polynomial of the form  $2^a \cdot 3^b$  are 512, 576, 648, 729, 768, 864, 972, 1024, 1152, 1296, 1458, 1536, 1728, 1944, 2048, 2187, and 2304.
- We choose 1152, 1536, and 2304, depending on the required security levels, where  $1152 = 2^7 \cdot 3^2$  and  $1536 = 2^9 \cdot 3$ . For the 256-bit security level, we choose two types of degrees as  $n = 2048 = 2^{11}$  and  $n = 2304 = 2^8 \cdot 3^2$ .
- Our modulus is chosen prime  $q$  that satisfies the NTT condition in NTTTRU KEM [17] using radix-3 and radix-2 NTT. NTTTRU KEM [17] shows that with appropriately chosen  $q$ , NTT over the ring  $\mathbb{Z}_{7681}[X]/(X^{768} - X^{384} + 1)$  is as fast as that over power-of-2 rings. In the case of  $n = 1152, 1536$ , and 2304,  $q$  is larger than  $2^{23}$  which lead to efficient rejection samplings. The parameter set of  $n = 2048$  has smaller output sizes than that with  $n = 2304$ , but the number of repetitions in the rejection samplings is 2 times larger than that of  $n = 2304$ . It is because that, compared to  $n = 2304$ , the modulus  $q$  is smaller than  $2^{23}$  and the size of  $\gamma_2$  is reduced by half.
- The concrete parameter set is presented in Table 5. As in the case of non-cyclotomic, LWE and SIS security is estimated using the script from <https://github.com/pq-crystals/security-estimates>. LWE cost by the lattice estimator is calculated from <https://github.com/malb/lattice-estimator>.

Our parameter choice is different from Dilithium [20, 34] and NTRU Prime KEM [9, 14].

- In NTRU Prime KEM [9, 14], the smallest  $p$  is 653 with  $q = 4621$ , but NCC-Sign Non-cyclotomic needs a larger  $p$  corresponding to much larger  $q$ . The main reason for this difference comes from the rejection sampling required in the signature scheme while it is not needed in KEM. The rejection sampling in signing makes the distribution of a signature independent from the secret key. For efficient rejection sampling, the larger  $q$  the better: it lowers the rejection probability. With larger  $q$ , we need larger  $p$  to thwart the lattice attacks.
- While Dilithium uses a single prime  $q$  for the modulus at all security levels,  $q$  in NCC-Sign is different at each security level since it needs an inert modulus  $q$  for each prime  $p$  in NCC-Sign Non-cyclotomic and an appropriate  $q$  for the use of incomplete NTT in NCC-Sign Trinomial.

**[NCC-Sign vs. Dilithium.]** We compare NCC-Sign and Dilithium in Table 6 in terms of the Core-SVP estimates for the LWE/SIS problems, output sizes and the expected number of repetitions. The classical Core-SVP estimates of Dilithium parameters are 123, 182, and 252 bits at the three security levels, respectively. However, the classical Core-SVP estimates of NCC-Sign parameters exceed or are close to 128, 192, and 256 bits at the three security levels and the expected number of repetitions in the rejection samplings are smaller than that of Dilithium.

**Table 6.** Comparison of Our Scheme and Dilithium

### 3.4 Security against Hybrid Dual Attacks

Recently, Bi, Lu, Luo, Wang and Zhang [10] present advanced hybrid dual attacks over the LWE problems for any secret distribution. Prior to their work, the hybrid attacks are only considered for sparse and/or small secrets. The bit-security estimations for Dilithium are indeed lower than the corresponding security levels as seen in Table 6. Moreover, the recent hybrid dual attacks on the LWE problems [10] further reduce the bit-security of Dilithium by 2 to 4 bits. The bit-security of LWE-based schemes is decreasing with the emergence of advanced attacks. Our parameter set at the security level 3 cannot achieve 192-bit security against the advanced hybrid dual attacks. Table 7 summarizes the bit-security estimations against the hybrid dual attack [10] under

core-SVP model of NCC-Sign-T and Dilithium. The estimations are calculated from <https://github.com/BiLei121/hybrid-dual-estimator>.

**Table 7.** Bit-security estimations against the hybrid dual attack under core-SVP model

Scheme	Security Level	Dual	Hybrid Dual [10]
Dilithium	2	124	122
	3	182	179
	5	251	247
NCC-Sign-T	1	132	129
	3	190.7	186
	5(5')	313.3(271.7)	306(265)

Our parameter set at the security level 3 with  $(n = 1536, q = 8257537)$  is measured as 186-bit security against the advanced hybrid dual attacks. To choose new parameter sets for NCC-Sign-T at the security level 3,  $\eta$  or  $n$  should be increased or  $q$  should be decreased for higher security.

- When increasing  $\eta$ : To increase the hardness of the LWE problem, it is possible to increase only  $\eta$  using the same  $n$  and  $q$ . Parameter set 3a using  $(n = 1536, q = 8257537, \eta = 2)$  results in 204-bit security against the hybrid dual attacks.
- When reducing  $q$ : If  $q$  is reduced for the same  $n$ , the LWE problem becomes harder. In parameter set 3b,  $(n = 1536, q = 5234689)$  can be used, and its bit-security against the hybrid dual attacks is 192.
- When increasing  $n$ : For higher security, the degree of the polynomial,  $n$ , can be increased. We can use  $n = 1728$  which requires a larger  $q = 25038721$ . This larger  $q$  reduces the expected number of repetitions in signing to 1.56 which is the smallest number of all our parameters.

Details of the three new parameters at the security level 3 are given in Table 8. Two parameter sets, 3b and 3c, are bandwidth-efficient version and speed-variant version, respectively.

**Table 8.** New parameter sets of NCC-Sign-T at the security level 3.

Parameter/Security Level	3a	3b	3c

## 4 Optimized Implementation on AVX2

We implement NCC-Sign Trinomial (NCC-Sign-T) and NCC-Sign Non-Cyclotomic (NCC-Sign-NC) on AVX2 by using the optimization techniques in the implementation of Dilithium [3].

### 4.1 NCC-Sign-T

For modular multiplication on AVX2, we use the signed Montgomery multiplication proposed in [33] to maintain the consistency of packed words. This allows 32-bit coefficients to be kept in 256-bit registers, with eight coefficients per register. Although recent methodologies such as improved Plantard multiplication [27] and Barrett multiplication [29] have been proposed, they require a double-word operand, making signed Montgomery multiplication a more natural choice from a packing perspective. Unlike Dilithium, applying NTT to the

trinomial-based cyclotomic ring requires a mixed approach of radix-2 and radix-3 divide-and-conquer techniques. In forward NTT, we first divide using radix-2 and then apply radix-3 decomposition. In iNTT, the order is reversed.

In NCC-Sign, the polynomial degrees and modulus  $q$  vary across all security levels, and thus, we employ an appropriate layer merging strategy for radix-2 and radix-3 decompositions tailored to each security level.

**Radix-2 NTT.** The radix-2 decomposition evaluates two coefficients through butterfly operations, arranging eight coefficients within vector registers and performing CT/GS butterfly based on signed Montgomery multiplication. When evaluating the complete trinomial polynomial in the initial layer, a modified version of the CT butterfly is used, although it is not significantly different. In NCC-Sign-T1, a 2-3-2-2 (radix-3) layer merging strategy is used, while in NCC-Sign-T3, a 3-3-2-1 strategy is applied, and in NCC-Sign-T5, a 3-3-2-2 (radix-3) strategy is employed. The last two layers in NCC-Sign-T1 and NCC-Sign-T5 are merged using radix-3 decomposition. For NCC-Sign-T3, the final radix-2 layer is computed independently. Although shuffling could be introduced to consider 3-3-3 merging, it is more advantageous to pack six coefficients into registers through separate layers rather than rearranging the eight packed coefficients into six, and to implement a pipelined structure with minimal register combinations. This approach avoids pipeline stalls due to complex shuffling and takes advantage of multiple issue execution.

**Radix-3 NTT.** The radix-3 decomposition evaluates three coefficients through butterfly operations. Unfortunately, since nine coefficients cannot be packed, the coefficients are packed six at a time within registers. In NCC-Sign-T1 and NCC-Sign-T5, as the polynomial is evaluated down to the coefficient level, the six packed coefficients require shuffling for 2-layer merging.

**Sampling.** Unlike the merging strategy and application of signed Montgomery multiplication within the complex NTT implementation using assembly code, non-NTT operations are written using intrinsics as there is minimal repeated access to the same memory addresses. The overall computational workload mainly arises from SHAKE-based sampling (e.g., `poly_uniform`, `poly_uniform_eta`), so we parallelize sampling in the same manner as in Dilithium [3]. For rejection sampling, we generate an index table to efficiently perform parallel sampling. To achieve this, we use AVX2 instructions `vpmovmskb` and `vpmovmskps` to extract sign bits and refer to the index table based on the extracted bits to perform parallel sampling. Since NCC-Sign-T uses the ring structure instead of the module structure, we cannot sample multiple polynomials within the module. Instead, we take an alternative engineering approach. To parallelize as many coefficients as possible and minimize the re-invocation of SHAKE, we allocate as much buffer as possible during the initial SHAKE call. After multiple trials, we found that allocating coefficients equivalent to six times the polynomial size in the buffer for `poly_uniform` yields the best performance. This approach is heuristic. Coefficients are sampled eight at a time, and similar to Dilithium [3], if more

sampling is required than the initial buffer allocation, the remaining coefficients are handled by the CPU.

**Table 9.** Cycle counts for reference implementations and AVX2 optimized implementation of **KeyGen** (K), **Sign** (S), and **Verify** (V) in NCC-Sign-T. Evaluation were performed on i7-13700K and the median value of 10,000 iterations was used. (Unit: cc)

Scheme		1	3	5
NCC-Sign-T (ref)	K	127,415	162,315	259,499
	S	250,128	421,926	704,288
	V	128,538	155,346	252,686
NCC-Sign-T (AVX2)	K	54,902	67,432	109,402
	S	89,207	165,766	261,423
	V	65,626	79,388	128,612
Dilithium (AVX2)	K	47,773	82,810	130,863
	S	109,176	180,271	238,143
	V	48,533	80,851	128,920

**Comparison.** Compared to Dilithium, NCC-Sign-T is faster than Dilithium at the security level 3, sign of NCC-Sign-T is 21% faster than Dilithium at the security level 1, and key generation of NCC-Sign-T is 18% faster than Dilithium at the security level 5. The rest of NCC-Sign-T are similar to or slower Dilithium. We believe our AVX2 optimized implementation has room for improvement if more optimization studies are conducted specifically for NCC-Sign-T.

## 4.2 NCC-Sign-NC

**NTT-based Multiplication.** NCC-Sign-NC uses the same Toom-Cook and Karatsuba algorithms as Saber. In [18], the NTT-unfriendly ring technique was proposed to apply NTT to Saber, which could not inherently utilize NTT, and it was shown that NTT is more efficient than the Toom-Cook and Karatsuba algorithms. When NTT can be applied, we expect NTT with a time complexity of  $O(n \log n)$  to be more effective in NCC-Sign-NC, which requires large polynomial multiplications. For this, we perform computations in NCC-Sign-NC by extending the cyclotomic minimal polynomial to  $x^{4096} + 1$ . Finally, we efficiently implement a 32-bit NTT on AVX2.

**NTT-Unfriendly Ring.** The core idea of the NTT-unfriendly ring proposed in [18] is to find an NTT-friendly  $q$  that is larger than the maximum value of the existing polynomial multiplication results. By performing NTT-based multiplication with this  $q'$  and then reducing the multiplication results to the original modulus  $q'$ , the same results can be obtained. From the calculations of the maximum value, we confirmed that 64-bit NTT multiplication is feasible.

**Small NTT.** In signing, since there are polynomial multiplications with small coefficients  $cs$  and  $ct$ , we can use a small, NTT-friendly  $q'$  based on this. The use

of a small  $q'$  provides an advantage in reduction during accumulated operations in NTT multiplication, allowing us to apply 32-bit NTT multiplication.

**Multi-moduli.** We confirmed that both 64-bit and 32-bit NTT multiplication are feasible in NCC-Sign-NC. Since there are no instructions in the AVX2 environment that directly support 64-bit multiplication, we utilize the multi-moduli technique proposed in [4] to replace 64-bit NTT-based multiplication with two 32-bit NTT-based multiplications. Similar to the NTT-unfriendly ring, the multi-moduli technique selects two NTT-friendly  $q'$  values such that their product is greater than the maximum value of the existing polynomial multiplication results. This approach overcomes the limitations of 64-bit operations and enables efficient computations.

As in the implementation of NCC-Sign-T, we use the signed Montgomery multiplication from [33] to maintain the consistency of packed words during modular multiplication in the AVX2 environment. This allows us to keep eight 32-bit coefficients in a 256-bit register for calculations. The same methodology is applied to NCC-Sign-NC, with the main difference being that in non-cyclotomic, we use the cyclotomic polynomial  $x^{4096} + 1$  and employ only the radix-2 divide-and-conquer method for NTT-based multiplication. In NCC-Sign-NC, we utilize the NTT-unfriendly and multi-moduli techniques to use the same cyclotomic polynomial  $x^{4096} + 1$  and modulus  $q'$  across all security levels.

**Radix-2 NTT.** In the radix-2 decomposition, two coefficients are evaluated through butterfly operations, just like in NCC-Sign-T, with eight coefficients arranged within vector registers, performing CT/GS butterfly based on signed Montgomery multiplication. Additionally, since the NTT-friendly  $q'$  used in NCC-Sign-NC's NTT multiplication is consistent across all security levels, a 3-3-6 layer merging strategy can be consistently applied to all security levels. In the final three layers, shuffling is employed to rearrange the positions of the coefficients, optimizing register utilization.

**Table 10.** Cycle counts for reference implementations and AVX2 optimized implementation in NCC-Sign-NC. Evaluation were performed on i7-13700K and the median value of 10,000 iterations was used. (Unit: cc)

## 5 Implementation on Cortex-M4

We implement NCC-Sign-T on Cortex-M4 using recent optimized techniques from Dilithium [5] and NTTTRU [17]. We use a NUCLEO-L4R5ZI board and arm-none-eabi-gcc version 10.2.1 with -O3 optimization. The board has 2 MiB of flash memory and 640 KiB of SRAM, and the benchmarking clock 89 frequency is 20 MHz. We adopt the same configuration as in [30].

Cycle counts for reference implementations of NCC-Sign-T and Dilithium are given in Table 11. Although NCC-Sign-T requires larger degrees than Dilithium for higher security, its reference implementation is faster than Dilithium.

**Table 11.** Cycle counts for reference implementations of NCC-Sign-T on Cortex-M4. Evaluation were performed on NUCLEO-L4R5ZI and the median value of 1,000 iterations was used. (Unit: cc)

Scheme	Variant		1		3		5	
			cc	stack	cc	stack	cc	stack
NCC-Sign-T	ref	K	2,140k	31.0k	2,795k	41.1k	4,236k	61.4k
		S	7,000k	49.3k	11,015k	65.4k	16,875k	97.7k
		V	3,110k	36.4k	3,944k	48.3k	6,159k	71.8k
Dilithium	ref	K	2,995k	37.4k	5,229k	59.4k	8,810k	95.4k
		S	10,034k	48.2k	16,005k	67.2k	20,969k	113.2k
		V	3,143k	35.3k	5,252k	56.3k	8,935k	90.6k

Since the two most time-consuming operations are SHAKE operations and NTT-based polynomial multiplication, the optimized implementation speeds up these two operations.

**Hashing.** NCC-Sign-T uses SHAKE-256 for generating random polynomial coefficients of the public key  $\mathbf{a}$ , hashing, and sampling  $y$ . SHAKE algorithms have Keccak at their core. We use the Keccak implementation from the XKCP project as in the pqm4 framework [30].

We implement a 32-bit NTT using the CT-butterfly and GS-butterfly from [25]. Additionally, [5] proposed a 3-layer merging implementation of radix-2 NTT in Dilithium. We apply this strategy to NCC-Sign-T. However, Trinomial parameter requires both radix-2 NTT and radix-3 NTT computations. Furthermore, since NCC-Sign-T uses different values of  $q$  for each security level, we implement it with optimal layer merging specific to each security level.

**Radix-2 NTT.** We implement the radix-2 NTT with up to 3-layer merging, following [5]. For NCC-Sign-T1, we apply 3-2-2 merging for 7 layers, for NCC-Sign-T3, 3-3-3 merging for 9 layers, and for NCC-Sign-T5, 3-3-2 merging for 8 layers.

**Radix-3 NTT.** NCC-Sign-T1 and NCC-Sign-T5 compute 2 layers for the radix-3 NTT. Similar to the radix-2 NTT, we use FPU registers to merge and compute

these 2 layers. NCC-Sign-T3 does not perform radix-3 NTT, so it handles this in the point-wise multiplication.

**Point-wise multiplication.** After NCC-Sign-T1 and NCC-Sign-T5 compute the complete NTT, so the point-wise multiplication is performed between monomials. We implement them in assembly codes, which removes all function call overhead. We omit the radix-3 NTT in NCC-Sign-T3 and handle it in point-wise multiplication, which is multiplication between quadratic polynomials. We use schoolbook multiplication to compute quadratic polynomial multiplication, efficiently utilizing the multiply-accumulate instruction, `smlal`, on the Cortex-M4.

Our optimized implementation is integrated into the pqm4 framework to measure performance. Table 12 lists the benchmarking results of our implementation, together with the cycle counts from Dilithium implementation in [30].

**Table 12.** Cycle counts and stack usage for NCC-Sign-T and Dilithium on Cortex-M4 using the pqm4 framework. Evaluation were performed on NUCLEO-L4R5ZI and the median value of 1,000 iterations was used. (Unit: cc)

Compared to Dilithium, although NCC-Sign-T require larger parameters for higher security, key generation, sign, and verify of NCC-Sign-T are at least 11% and at most 71% faster than those of Dilithium. It is also about 28%, 41% and 42% faster than Dilithium in terms of **KeyGen+Sign+Verify** at the three security levels, respectively. Our results show better performance despite not applying advanced optimization techniques such as Fermat Number Transform (FNT) introduced in [5]. Faster performance of NCC-Sign-T over Dilithium is due to the fact that NCC-Sign-T based on the ring structure requires fewer polynomial coefficients than Dilithium based on the module structure, and the number of repetitions in the rejection samplings for signing in NCC-Sign-T is smaller than that of Dilithium. They result in fewer calls to SHAKE in the sampling process and fewer aborts in signing. NCC-Sign-T also shows better results than Dilithium in stack usage for all parameter sets. NCC-Sign-T is well suited for low-cost constrained devices. We believe that further performance improvements are possible if more optimization studies are conducted specifically for NCC-Sign-T.
